GREEN DROP Tree Care

What It Is:

A slow release - liquid fertilizer should be injected directly into the ground around the tree roots in the fall or spring. It can be done up to twice a year and it may be more beneficial for certain trees to be done twice.

This method involves injecting a liquid fertilizer 6–8 inches below the soil surface, right where the roots need it most. Instead of sprinkling nutrients on the surface and hoping they make their way down, we skip the guessing game and go straight to the source.

To ensure every root gets its fair share, we use specialized equipment to distribute the fertilizer evenly across the tree's root zone. This means injecting the nutrients under the canopy and extending to the drip line (the edge of the tree's branches). It's a systematic, science-backed approach designed to optimize tree health and growth.

When you fertilize from the top, nutrients slowly move through the soil and along the way, they may get snagged by competing plants or washed away by rain.

Trees in their natural forest setting will obtain crucial nutrients from the abundant decomposing leaf and other litter found on the forest floor... BUT, in the urban landscape - leaf litter and grass clippings are usually raked up and removed so there are no naturally available nutrients!

Unless you recently or regularly add nutrients to the soil around your trees, they are definitely nutrient deficient!
